Salifort Motors ML project

April 13, 2024

1 Salifort Motors Classification project: Providing data-driven suggestions for HR

1.0.1 Understand the business scenario and problem

The HR department at Salifort Motors wants to take some initiatives to improve employee satisfaction levels at the company. They collected data from employees, but now they don't know what to do with it. They refer to you as a data analytics professional and ask you to provide data-driven suggestions based on your understanding of the data. They have the following question: what's likely to make the employee leave the company?

Your goals in this project are to analyze the data collected by the HR department and to build a model that predicts whether or not an employee will leave the company.

If you can predict employees likely to quit, it might be possible to identify factors that contribute to their leaving. Because it is time-consuming and expensive to find, interview, and hire new employees, increasing employee retention will be beneficial to the company.

1.0.2 Familiarize yourself with the HR dataset

In this dataset, there are 14,999 rows, 10 columns, and these variables:

Variable	Description
satisfaction_level	Employee-reported job satisfaction level [0–1]
last_evaluation	Score of employee's last performance review [0–1]
number_project	Number of projects employee contributes to
average_monthly_hours	Average number of hours employee worked per month
time_spend_company	How long the employee has been with the company (years)
Work_accident	Whether or not the employee experienced an accident while at work
left	Whether or not the employee left the company
promotion_last_5years	Whether or not the employee was promoted in
	the last 5 years
Department	The employee's department
salary	The employee's salary (U.S. dollars)

1.1 Step 1. Imports

- Import packages
- Load dataset

1.1.1 Import packages

```
[1]: # Import packages
     ### YOUR CODE HERE ###
     # For data manipulation
     import numpy as np
     import pandas as pd
     # For data visualization
     import matplotlib.pyplot as plt
     import seaborn as sns
     # For displaying all of the columns in dataframes
     pd.set_option('display.max_columns', None)
     # For data modeling
     from xgboost import XGBClassifier
     from xgboost import XGBRegressor
     from xgboost import plot_importance
     from sklearn.linear_model import LogisticRegression
     from sklearn.tree import DecisionTreeClassifier
     from sklearn.ensemble import RandomForestClassifier
     # For metrics and helpful functions
     from sklearn.model_selection import GridSearchCV, train_test_split
     from sklearn.metrics import accuracy_score, precision_score, recall_score,\
     f1 score, confusion matrix, ConfusionMatrixDisplay, classification report
     from sklearn.metrics import roc_auc_score, roc_curve
     from sklearn.tree import plot_tree
     # For saving models
     import pickle
```

1.1.2 Load dataset

```
[2]: # RUN THIS CELL TO IMPORT YOUR DATA.

# Load dataset into a dataframe
### YOUR CODE HERE ###

df0 = pd.read_csv("HR_capstone_dataset.csv")
```

```
# Display first few rows of the dataframe
### YOUR CODE HERE ###
df0.head()
```

```
[2]:
        satisfaction_level last_evaluation number_project
                                                               average_montly_hours \
                       0.38
                                         0.53
                                                                                   157
                       0.80

```

1.2 Step 2. Data Exploration (Initial EDA and data cleaning)

- Understand your variables
- Clean your dataset (missing data, redundant data, outliers)

1.2.1 Gather basic information about the data

```
[3]: # Gather basic information about the data
### YOUR CODE HERE ###
df0.info()
```

<class 'pandas.core.frame.DataFrame'>
RangeIndex: 14999 entries, 0 to 14998
Data columns (total 10 columns):

#	Column	Non-Null Count	Dtype
0	satisfaction_level	14999 non-null	float64
1	last_evaluation	14999 non-null	float64
2	number_project	14999 non-null	int64
3	average_montly_hours	14999 non-null	int64
4	time_spend_company	14999 non-null	int64
5	Work_accident	14999 non-null	int64
6	left	14999 non-null	int64

```
7 promotion_last_5years 14999 non-null int64
8 Department 14999 non-null object
9 salary 14999 non-null object
```

dtypes: float64(2), int64(6), object(2)

memory usage: 1.1+ MB

1.2.2 Gather descriptive statistics about the data

```
[4]: # Gather descriptive statistics about the data ### YOUR CODE HERE ### df0.describe()
```

[4]:		satisfaction_level	last_evaluation	number_project \		
	count	14999.000000	14999.000000	14999.000000		
	mean	0.612834	0.716102	3.803054		
	std	0.248631	0.171169	1.232592		
	min	0.090000	0.360000	2.000000		
	25%	0.440000	0.560000	3.000000		
	50%	0.640000	0.720000	4.000000		
	75%	0.820000	0.870000	5.000000		
	max	1.000000	1.000000	7.000000		
		average_montly_hours	time_spend_comp	pany Work_accident	left	\
	count	14999.000000	14999.000	0000 14999.000000	14999.000000	
	mean	201.050337	3.498	0.144610	0.238083	
	std	49.943099	1.460	0.351719	0.425924	
	min	96.000000	2.000	0.000000	0.000000	
	25%	156.000000	3.000	0.000000	0.000000	
	50%	200.000000	3.000	0.000000	0.000000	
	75%	245.000000	4.000	0.000000	0.000000	
	max	310.000000	10.000	1.000000	1.000000	
		promotion_last_5year	S			
	count	14999.00000	0			
	mean	0.02126	8			
	std	0.14428	1			
	min	0.00000	0			
	25%	0.00000	0			
	50%	0.00000	0			
	75%	0.00000	0			
	max	1.00000	0			

1.2.3 Rename columns

As a data cleaning step, rename the columns as needed. Standardize the column names so that they are all in snake_case, correct any column names that are misspelled, and make column names more concise as needed.

```
[5]: # Display all column names
### YOUR CODE HERE ###
df0.columns
```

1.2.4 Check missing values

Check for any missing values in the data.

```
[7]: # Check for missing values
### YOUR CODE HERE ###
df0.isna().sum()
```

```
[7]: satisfaction_level
                               0
     last evaluation
                               0
    number_project
                               0
     average_monthly_hours
     tenure
                               0
     work_accident
                               0
     left
                               0
    promotion_last_5years
                               0
     department
                               0
                               0
     salary
     dtype: int64
```

There are no missing values in the data.

1.2.5 Check duplicates

Check for any duplicate entries in the data.

```
[8]: # Check for duplicates
### YOUR CODE HERE ###
df0.duplicated().sum()
```

[8]: 3008

 $3{,}008$ rows contain duplicates. That is 20% of the data.

```
[9]: # Inspect some rows containing duplicates as needed
### YOUR CODE HERE ###
df0[df0.duplicated()].head()
```

[9]:	satisfaction_level	last e	valuati	on number	project	\
396	-	1420_0	0.	_	2	`
866			0.		2	
131			0.		2	
136			0.		2	
146			0.		2	
	0.12		٠.		-	
	average_monthly_hour	rs ten	ure wo	rk_accident	left	\
396	3	39	3	0	1	
866	3	28	3	0	1	
131	.7	27	3	0	1	
136	58 13	32	3	0	1	
146	51 14	42	3	0	1	
	promotion_last_5year	rs dep	artment	salary		
396	3	0	sales	low		
866	3	0 acc	ounting	low		
131	.7	0	sales	medium		
136	88	0	RandD	low		
146	31	0	sales	low		

The above output shows the first five occurrences of rows that are duplicated farther down in the dataframe. How likely is it that these are legitimate entries? In other words, how plausible is it that two employees self-reported the exact same response for every column?

```
[10]: # Drop duplicates and save resulting dataframe in a new variable as needed
### YOUR CODE HERE ###
df1 = df0.drop_duplicates(keep='first')

# Display first few rows of new dataframe as needed
df1.head()
```

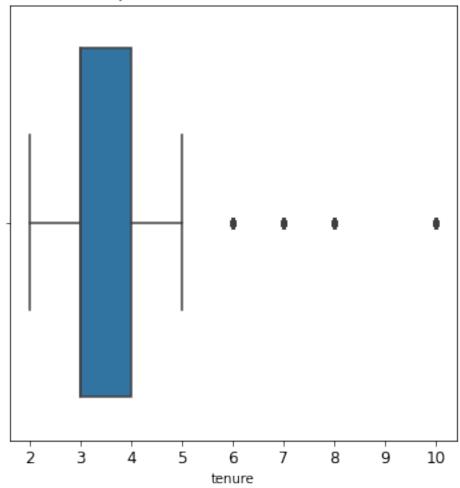

```
[10]:

                             0
                                    1
                                                            0
                                                                   sales
                                                                             low
      4
              3
                             0
                                    1
                                                            0
                                                                   sales
                                                                             low
```

1.2.6 Check outliers

Check for outliers in the data.

```
[11]: # Create a boxplot to visualize distribution of `tenure` and detect any outliers
plt.figure(figsize=(6,6))
plt.title('Boxplot to detect outliers for tenure', fontsize=12)
plt.xticks(fontsize=12)
plt.yticks(fontsize=12)
sns.boxplot(x=df1['tenure'])
plt.show()
```

The boxplot above shows that there are outliers in the tenure variable.

It would be helpful to investigate how many rows in the data contain outliers in the tenure column.

```
[1]: # Determine the number of rows containing outliers
    ### YOUR CODE HERE ###

# Compute the 25th percentile value in `tenure`
percentile25 = df1['tenure'].quantile(0.25)

# Compute the 75th percentile value in `tenure`
percentile75 = df1['tenure'].quantile(0.75)

# Compute the interquartile range in `tenure`
iqr = percentile75 - percentile25
```

```
NameError Traceback (most recent call last)

```

Certain types of models are more sensitive to outliers than others. When you get to the stage of building your model, consider whether to remove these outliers based on the type of model you decide to use.

1.3 Step 2. Data Exploration (Continue EDA)

Begin by understanding how many employees left and what percentage of all employees this figure represents.

```
[13]: # Get numbers of people who left vs. stayed
    ### YOUR CODE HERE ###
    print(df1['left'].value_counts())
    print()

# Get percentages of people who left vs. stayed
    ### YOUR CODE HERE ###
    print(df1['left'].value_counts(normalize=True))

0    10000
1    1991
Name: left, dtype: int64

0    0.833959
```

```
1 0.166041
Name: left, dtype: float64
```

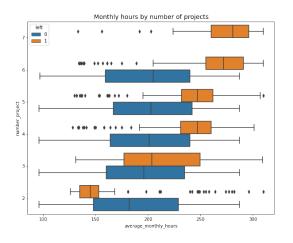

1.3.1 Data visualizations

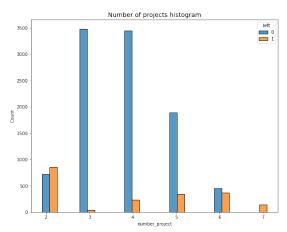

Now, examine variables that you're interested in, and create plots to visualize relationships between variables in the data.

You could start by creating a stacked boxplot showing average_monthly_hours distributions for number project, comparing the distributions of employees who stayed versus those who left.

Box plots are very useful in visualizing distributions within data, but they can be deceiving without the context of how big the sample sizes that they represent are. So, you could also plot a stacked histogram to visualize the distribution of number project for those who stayed and those who left.

```
[14]: # Create a plot as needed
      ### YOUR CODE HERE ###
      # Set figure and axes
      fig, ax = plt.subplots(1, 2, figsize = (22,8))
      # Create boxplot showing `average_monthly_hours` distributions for_
       - `number project`, comparing employees who stayed versus those who left
      sns.boxplot(data=df1, x='average monthly hours', y='number project', |
       ⇔hue='left', orient="h", ax=ax[0])
      ax[0].invert yaxis()
      ax[0].set_title('Monthly hours by number of projects', fontsize='14')
      # Create histogram showing distribution of `number_project`, comparing_
       ⇔employees who stayed versus those who left
      tenure stay = df1[df1['left']==0]['number project']
      tenure left = df1[df1['left']==1]['number project']
      sns.histplot(data=df1, x='number_project', hue='left', multiple='dodge', __
       ⇒shrink=2, ax=ax[1])
      ax[1].set_title('Number of projects histogram', fontsize='14')
      # Display the plots
      plt.show()
```

It might be natural that people who work on more projects would also work longer hours. This appears to be the case here, with the mean hours of each group (stayed and left) increasing with number of projects worked. However, a few things stand out from this plot.

- 1. There are two groups of employees who left the company: (A) those who worked considerably less than their peers with the same number of projects, and (B) those who worked much more. Of those in group A, it's possible that they were fired. It's also possible that this group includes employees who had already given their notice and were assigned fewer hours because they were already on their way out the door. For those in group B, it's reasonable to infer that they probably quit. The folks in group B likely contributed a lot to the projects they worked in; they might have been the largest contributors to their projects.
- 2. Everyone with seven projects left the company, and the interquartile ranges of this group and those who left with six projects was $\sim 255-295$ hours/month—much more than any other group.
- 3. The optimal number of projects for employees to work on seems to be 3–4. The ratio of left/stayed is very small for these cohorts.
- 4. If you assume a work week of 40 hours and two weeks of vacation per year, then the average number of working hours per month of employees working Monday-Friday = 50 weeks * 40 hours per week / 12 months = 166.67 hours per month. This means that, aside from the employees who worked on two projects, every group—even those who didn't leave the company—worked considerably more hours than this. It seems that employees here are overworked.

As the next step, you could confirm that all employees with seven projects left.

```
[15]: # Get value counts of stayed/left for employees with 7 projects df1[df1['number_project']==7]['left'].value_counts()
```

[15]: 1 145 Name: left, dtype: int64

This confirms that all employees with 7 projects did leave.

Next, you could examine the average monthly hours versus the satisfaction levels.

```
[16]: # Create a plot as needed
### YOUR CODE HERE ###

# Create scatterplot of `average_monthly_hours` versus `satisfaction_level`,
comparing employees who stayed versus those who left
plt.figure(figsize=(16, 9))
sns.scatterplot(data=df1, x='average_monthly_hours', y='satisfaction_level',
hue='left', alpha=0.4)
plt.axvline(x=166.67, color='#ff6361', label='166.67 hrs./mo.', ls='--')
plt.legend(labels=['166.67 hrs./mo.', 'left', 'stayed'])
plt.title('Monthly hours by last evaluation score', fontsize='14');
```

The scatterplot above shows that there was a sizeable group of employees who worked $\sim 240-315$ hours per month. 315 hours per month is over 75 hours per week for a whole year. It's likely this is related to their satisfaction levels being close to zero.

The plot also shows another group of people who left, those who had more normal working hours. Even so, their satisfaction was only around 0.4. It's difficult to speculate about why they might have left. It's possible they felt pressured to work more, considering so many of their peers worked more. And that pressure could have lowered their satisfaction levels.

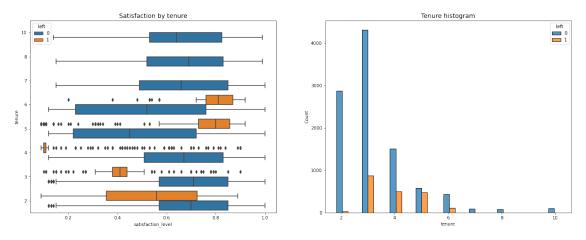

Finally, there is a group who worked $\sim 210-280$ hours per month, and they had satisfaction levels ranging $\sim 0.7-0.9$.

Note the strange shape of the distributions here. This is indicative of data manipulation or synthetic data.

For the next visualization, it might be interesting to visualize satisfaction levels by tenure.

```
[17]: # Create a plot as needed
      ### YOUR CODE HERE ###
      # Set figure and axes
      fig, ax = plt.subplots(1, 2, figsize = (22,8))
      # Create boxplot showing distributions of `satisfaction level` by tenure,
       ⇔comparing employees who stayed versus those who left
      sns.boxplot(data=df1, x='satisfaction_level', y='tenure', hue='left',__

orient="h", ax=ax[0])
      ax[0].invert yaxis()
      ax[0].set_title('Satisfaction by tenure', fontsize='14')
      # Create histogram showing distribution of `tenure`, comparing employees whou
       ⇔stayed versus those who left
      tenure_stay = df1[df1['left']==0]['tenure']
      tenure_left = df1[df1['left']==1]['tenure']
      sns.histplot(data=df1, x='tenure', hue='left', multiple='dodge', shrink=5,_
       \Rightarrowax=ax[1])
      ax[1].set_title('Tenure histogram', fontsize='14')
      plt.show();
```

There are many observations you could make from this plot. - Employees who left fall into two general categories: dissatisfied employees with shorter tenures and very satisfied employees with medium-length tenures. - Four-year employees who left seem to have an unusually low satisfaction level. It's worth investigating changes to company policy that might have affected people specifically at the four-year mark, if possible. - The longest-tenured employees didn't leave. Their satisfaction levels aligned with those of newer employees who stayed. - The histogram shows that there are relatively few longer-tenured employees. It's possible that they're the higher-ranking, higher-paid

employees.

As the next step in analyzing the data, you could calculate the mean and median satisfaction scores of employees who left and those who didn't.

```
[18]: # Calculate mean and median satisfaction scores of employees who left and those who stayed df1.groupby(['left'])['satisfaction_level'].agg([np.mean,np.median])
```

```
[18]: mean median left 0 0.667365 0.69 1 0.440271 0.41
```

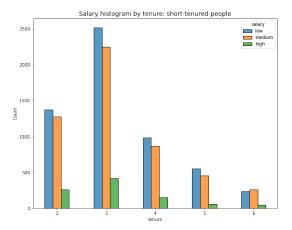

As expected, the mean and median satisfaction scores of employees who left are lower than those of employees who stayed. Interestingly, among employees who stayed, the mean satisfaction score appears to be slightly below the median score. This indicates that satisfaction levels among those who stayed might be skewed to the left.

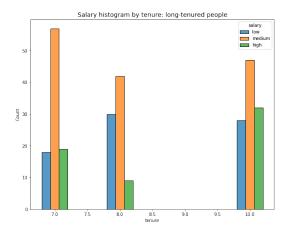

Next, you could examine salary levels for different tenures.

```
[19]: # Create a plot as needed
      ### YOUR CODE HERE ###
      # Set figure and axes
      fig, ax = plt.subplots(1, 2, figsize = (22,8))
      # Define short-tenured employees
      tenure_short = df1[df1['tenure'] < 7]</pre>
      # Define long-tenured employees
      tenure_long = df1[df1['tenure'] > 6]
      # Plot short-tenured histogram
      sns.histplot(data=tenure_short, x='tenure', hue='salary', discrete=1,
                    hue_order=['low', 'medium', 'high'], multiple='dodge', shrink=.5, __
       \Rightarrowax=ax[0])
      ax[0].set_title('Salary histogram by tenure: short-tenured people', __

¬fontsize='14')
      # Plot long-tenured histogram
      sns.histplot(data=tenure_long, x='tenure', hue='salary', discrete=1,
                   hue_order=['low', 'medium', 'high'], multiple='dodge', shrink=.4,__
       \Rightarrowax=ax[1])
      ax[1].set_title('Salary histogram by tenure: long-tenured people', __

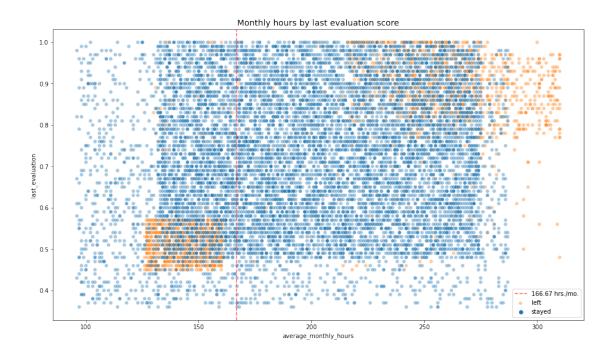

¬fontsize='14');
```

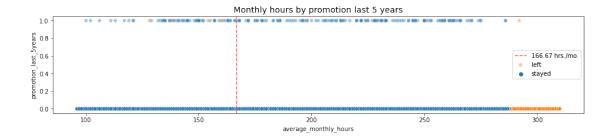

The plots above show that long-tenured employees were not disproportionately comprised of higher-paid employees.

Next, you could explore whether there's a correlation between working long hours and receiving high evaluation scores. You could create a scatterplot of average_monthly_hours versus last_evaluation.

The following observations can be made from the scatterplot above: - The scatterplot indicates two groups of employees who left: overworked employees who performed very well and employees who worked slightly under the nominal monthly average of 166.67 hours with lower evaluation scores. - There seems to be a correlation between hours worked and evaluation score. - There isn't a high percentage of employees in the upper left quadrant of this plot; but working long hours doesn't guarantee a good evaluation score. - Most of the employees in this company work well over 167 hours per month.

Next, you could examine whether employees who worked very long hours were promoted in the last five years.

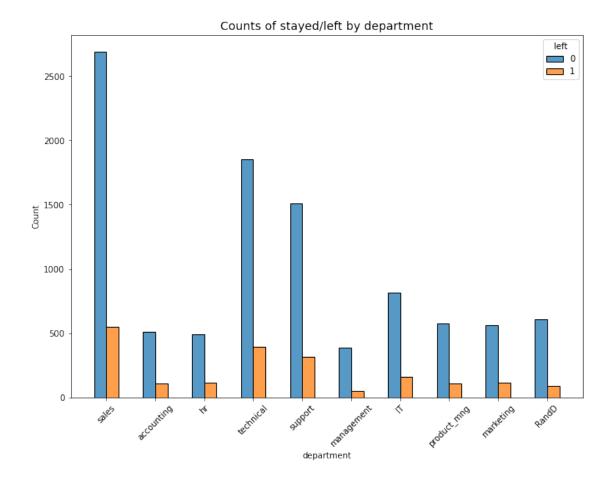

The plot above shows the following: - very few employees who were promoted in the last five years left - very few employees who worked the most hours were promoted - all of the employees who left were working the longest hours

Next, you could inspect how the employees who left are distributed across departments.

```
[22]: # Display counts for each department
df1["department"].value_counts()
```

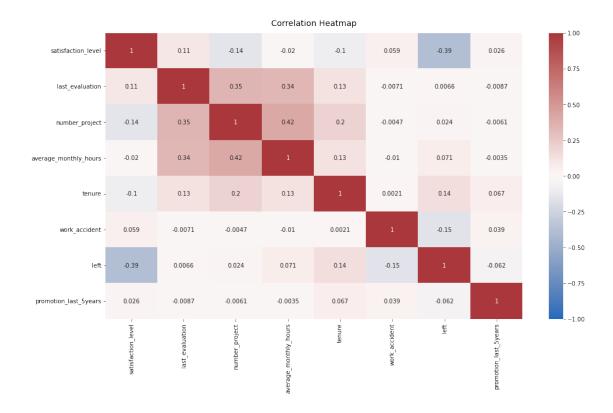

```
[22]: sales
                      3239
      technical
                      2244
      support
                      1821
      IT
                       976
                       694
      RandD
      product_mng
                       686
      marketing
                       673
      accounting
                       621
      hr
                       601
                       436
      management
```

Name: department, dtype: int64

There doesn't seem to be any department that differs significantly in its proportion of employees who left to those who stayed.

Lastly, you could check for strong correlations between variables in the data.

The correlation heatmap confirms that the number of projects, monthly hours, and evaluation scores all have some positive correlation with each other, and whether an employee leaves is negatively correlated with their satisfaction level.

1.3.2 Insights

It appears that employees are leaving the company as a result of poor management. Leaving is tied to longer working hours, many projects, and generally lower satisfaction levels. It can be ungratifying to work long hours and not receive promotions or good evaluation scores. There's a sizeable group of employees at this company who are probably burned out. It also appears that if an employee has spent more than six years at the company, they tend not to leave.

2 paCe: Construct Stage

- Determine which models are most appropriate
- Construct the model
- Confirm model assumptions
- Evaluate model results to determine how well your model fits the data

Recall model assumptions

Logistic Regression model assumptions - Outcome variable is categorical - Observations are independent of each other - No severe multicollinearity among X variables - No extreme outliers - Linear relationship between each X variable and the logit of the outcome variable - Sufficiently

2.1 Step 3. Model Building, Step 4. Results and Evaluation

- Fit a model that predicts the outcome variable using two or more independent variables
- Check model assumptions
- Evaluate the model

2.1.1 Identify the type of prediction task.

Your goal is to predict whether an employee leaves the company, which is a categorical outcome variable. So this task involves classification. More specifically, this involves binary classification, since the outcome variable left can be either 1 (indicating employee left) or 0 (indicating employee didn't leave).

2.1.2 Identify the types of models most appropriate for this task.

Since the variable we want to predict (whether an employee leaves the company) is categorical, we could either build a Logistic Regression model, or a Tree-based Machine Learning model.

So we could proceed with one of the two following approaches. Or, we could implement both and determine how they compare.

2.1.3 Modeling Approach A: Logistic Regression Model

This approach covers implementation of Logistic Regression.

Logistic regression Note that binomial logistic regression suits the task because it involves binary classification.

Before splitting the data, encode the non-numeric variables. There are two: department and salary.

department is a categorical variable, which means you can dummy it for modeling.

salary is categorical too, but it's ordinal. There's a hierarchy to the categories, so it's better not to dummy this column, but rather to convert the levels to numbers, 0–2.

```
[25]: # Copy the dataframe
df_enc = df1.copy()

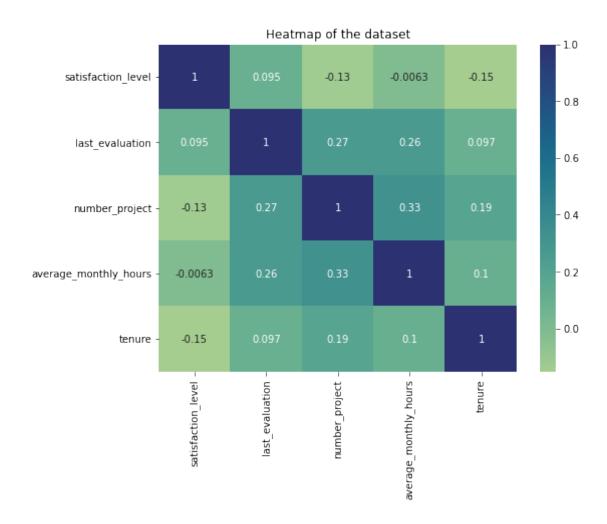

# Encode the `salary` column as an ordinal numeric category
df_enc['salary'] = (
    df_enc['salary'].astype('category')
    .cat.set_categories(['low', 'medium', 'high'])
    .cat.codes
)

# Dummy encode the `department` column
df_enc = pd.get_dummies(df_enc, drop_first=False)
```

```
# Display the new dataframe
df_enc.head()
```

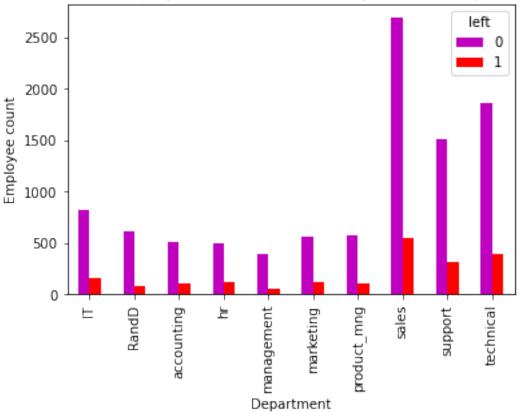

```
[25]:
         satisfaction_level last_evaluation number_project
                                                                  average_monthly_hours
                         0.38
                                           0.53
                                                                                        157
      0
                                                                2
      1
                         0.80
                                           0.86
                                                                5
                                                                                        262
                                                                7
      2
                         0.11
                                           0.88
                                                                                        272
                         0.72
      3
                                           0.87
                                                                5
                                                                                        223
                         0.37
                                           0.52
                                                                2
                                                                                        159
                                   left promotion_last_5years
                  work_accident
                                                                 salary
                                                                           department_IT \
         tenure
      0

                          1
```

Create a heatmap to visualize how correlated variables are. Consider which variables you're interested in examining correlations between.

Create a stacked bart plot to visualize number of employees across department, comparing those who left with those who didn't.

Since logistic regression is quite sensitive to outliers, it would be a good idea at this stage to remove the outliers in the tenure column that were identified earlier.

```

Isolate the outcome variable, which is the variable you want your model to predict.

```
[29]: # Isolate the outcome variable
y = df_logreg['left']

# Display first few rows of the outcome variable
y.head()
```

[29]: 0 1
 2 1
 3 1
 4 1
 5 1
 Name: left, dtype: int64

Select the features you want to use in your model. Consider which variables will help you predict the outcome variable, left.

```
[30]: # Select the features you want to use in your model
X = df_logreg.drop('left', axis=1)
```

```
# Display the first few rows of the selected features
      X.head()

                                                                        0
      4
                          1
                                                0
                                                                        0
```

Split the data into training set and testing set. Don't forget to stratify based on the values in y, since the classes are unbalanced.

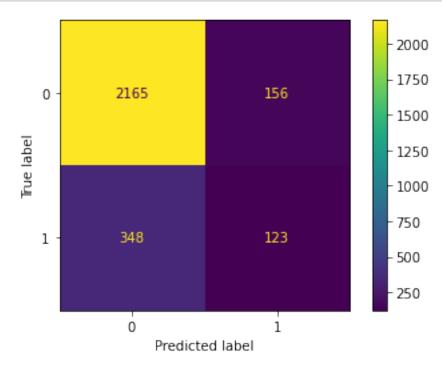

```
[31]: # Split the data into training set and testing set
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.25,__
stratify=y, random_state=42)
```

Construct a logistic regression model and fit it to the training dataset.

Test the logistic regression model: use the model to make predictions on the test set.

```
[33]: # Use the logistic regression model to get predictions on the test set y_pred = log_clf.predict(X_test)
```

Create a confusion matrix to visualize the results of the logistic regression model.

The upper-left quadrant displays the number of true negatives. The upper-right quadrant displays the number of false positives. The bottom-left quadrant displays the number of false negatives.

The bottom-right quadrant displays the number of true positives.

True negatives: The number of people who did not leave that the model accurately predicted did not leave.

False positives: The number of people who did not leave the model inaccurately predicted as leaving.

False negatives: The number of people who left that the model inaccurately predicted did not leave

True positives: The number of people who left the model accurately predicted as leaving

A perfect model would yield all true negatives and true positives, and no false negatives or false positives.

Create a classification report that includes precision, recall, f1-score, and accuracy metrics to evaluate the performance of the logistic regression model.

Check the class balance in the data. In other words, check the value counts in the left column. Since this is a binary classification task, the class balance informs the way you interpret accuracy metrics.

```
[35]: df_logreg['left'].value_counts(normalize=True)
```

[35]: 0 0.831468 1 0.168532

Name: left, dtype: float64

There is an approximately 83%-17% split. So the data is not perfectly balanced, but it is not too imbalanced. If it was more severely imbalanced, you might want to resample the data to make it more balanced. In this case, you can use this data without modifying the class balance and continue evaluating the model.

```
[36]: # Create classification report for logistic regression model target_names = ['Predicted would not leave', 'Predicted would leave'] print(classification_report(y_test, y_pred, target_names=target_names))
```

	precision	recall	f1-score	support
	_			
Predicted would not leave	0.86	0.93	0.90	2321
Predicted would leave	0.44	0.26	0.33	471
accuracy			0.82	2792
macro avg	0.65	0.60	0.61	2792
weighted avg	0.79	0.82	0.80	2792

The classification report above shows that the logistic regression model achieved a precision of 79%, recall of 82%, f1-score of 80% (all weighted averages), and accuracy of 82%. However, if it's most important to predict employees who leave, then the scores are significantly lower.

2.1.4 Modeling Approach B: Tree-based Model

This approach covers implementation of Decision Tree and Random Forest.

Isolate the outcome variable.

```
[37]: # Isolate the outcome variable
      y = df_enc['left']
      # Display the first few rows of `y`
      y.head()
[37]: 0
           1
      1
           1
      2
           1
      3
            1
           1
      Name: left, dtype: int64
     Select the features.
[38]: # Select the features
      X = df_enc.drop('left', axis=1)
      # Display the first few rows of `X`
      X.head()
                                                                  average_monthly_hours
[38]:
         satisfaction_level
                               last_evaluation number_project
                        0.38

Split the data into training, validating, and testing sets.

```
[39]: # Split the data
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.25, u

→stratify=y, random_state=0)
```

Decision tree - Round 1 Construct a decision tree model and set up cross-validated grid-search to exhuastively search for the best model parameters.

Fit the decision tree model to the training data.

Identify the optimal values for the decision tree parameters.

```
[42]: # Check best parameters tree1.best_params_
```

[42]: {'max_depth': 4, 'min_samples_leaf': 5, 'min_samples_split': 2}

Identify the best AUC score achieved by the decision tree model on the training set.

```
[43]: # Check best AUC score on CV tree1.best_score_
```

[43]: 0.969819392792457

This is a strong AUC score, which shows that this model can predict employees who will leave very well.

Next, you can write a function that will help you extract all the scores from the grid search.

```
# Create dictionary that maps input metric to actual metric name in
\hookrightarrow GridSearchCV
  metric_dict = {'auc': 'mean_test_roc_auc',
                  'precision': 'mean test precision',
                  'recall': 'mean_test_recall',
                  'f1': 'mean test f1',
                  'accuracy': 'mean test accuracy'
                 }
  # Get all the results from the CV and put them in a df
  cv_results = pd.DataFrame(model_object.cv_results_)
  # Isolate the row of the df with the max(metric) score
  best_estimator_results = cv_results.iloc[cv_results[metric_dict[metric]].
→idxmax(), :]
  # Extract Accuracy, precision, recall, and f1 score from that row
  auc = best_estimator_results.mean_test_roc_auc
  f1 = best_estimator_results.mean_test_f1
  recall = best_estimator_results.mean_test_recall
  precision = best_estimator_results.mean_test_precision
  accuracy = best_estimator_results.mean_test_accuracy
  # Create table of results
  table = pd.DataFrame()
  table = pd.DataFrame({'model': [model_name],
                         'precision': [precision],
                         'recall': [recall],
                         'F1': [f1],
                         'accuracy': [accuracy],
                         'auc': [auc]
                       })
  return table
```

Use the function just defined to get all the scores from grid search.

```
[45]: # Get all CV scores

tree1_cv_results = make_results('decision tree cv', tree1, 'auc')

tree1_cv_results
```

```
[45]: model precision recall F1 accuracy auc 0 decision tree cv 0.914552 0.916949 0.915707 0.971978 0.969819
```

All of these scores from the decision tree model are strong indicators of good model performance.

Recall that decision trees can be vulnerable to overfitting, and random forests avoid overfitting by incorporating multiple trees to make predictions. You could construct a random forest model next.

Random forest - Round 1 Construct a random forest model and set up cross-validated gridsearch to exhuastively search for the best model parameters.

```
[46]: # Instantiate model
      rf = RandomForestClassifier(random_state=0)
      # Assign a dictionary of hyperparameters to search over
      cv_params = {'max_depth': [3,5, None],
                   'max features': [1.0],
                   'max_samples': [0.7, 1.0],
                   'min samples leaf': [1,2,3],
                   'min_samples_split': [2,3,4],
                   'n estimators': [300, 500],
                   }
      # Assign a dictionary of scoring metrics to capture
      scoring = {'accuracy', 'precision', 'recall', 'f1', 'roc_auc'}
      # Instantiate GridSearch
      rf1 = GridSearchCV(rf, cv_params, scoring=scoring, cv=4, refit='roc auc')
```

Fit the random forest model to the training data.

```
[47]: %%time
      rf1.fit(X_train, y_train) # --> Wall time: ~10min
     CPU times: user 9min 7s, sys: 3.01 s, total: 9min 10s
     Wall time: 9min 10s
[47]: GridSearchCV(cv=4, error_score=nan,
                   estimator=RandomForestClassifier(bootstrap=True, ccp_alpha=0.0,
                                                     class_weight=None,

scoring={'f1', 'precision', 'accuracy', 'roc_auc', 'recall'},
verbose=0)
```

Specify path to where you want to save your model.

```
[48]: # Define a path to the folder where you want to save the model
path = '/home/jovyan/work/'
```

Define functions to pickle the model and read in the model.

Use the functions defined above to save the model in a pickle file and then read it in.

```
[51]: # Write pickle write_pickle(path, rf1, 'hr_rf1')
```

```
[52]: # Read pickle
rf1 = read_pickle(path, 'hr_rf1')
```

Identify the best AUC score achieved by the random forest model on the training set.

```
[53]: # Check best AUC score on CV rf1.best_score_
```

[53]: 0.9804250949807172

Identify the optimal values for the parameters of the random forest model.

```
[54]: # Check best params rf1.best_params_
```

```
[54]: {'max_depth': 5,
    'max_features': 1.0,
    'max_samples': 0.7,
    'min_samples_leaf': 1,
    'min_samples_split': 4,
    'n_estimators': 500}
```

Collect the evaluation scores on the training set for the decision tree and random forest models.

```
[55]: # Get all CV scores
    rf1_cv_results = make_results('random forest cv', rf1, 'auc')
    print(tree1_cv_results)
    print(rf1_cv_results)
```

```
model precision
                               recall
                                             F1
                                                 accuracy
                                                                 auc
decision tree cv
                   0.914552
                             0.916949
                                       0.915707
                                                 0.971978
                                                            0.969819
           model
                  precision
                               recall
                                             F1
                                                 accuracy
random forest cv
                   0.950023
                             0.915614 0.932467
                                                 0.977983
                                                            0.980425
```

The evaluation scores of the random forest model are better than those of the decision tree model, with the exception of recall (the recall score of the random forest model is approximately 0.001 lower, which is a negligible amount). This indicates that the random forest model mostly outperforms the decision tree model.

Next, you can evaluate the final model on the test set.

Define a function that gets all the scores from a model's predictions.

```
Out: pandas df of precision, recall, f1, accuracy, and AUC scores for <math>your_{\perp}
\hookrightarrow model
   111
  preds = model.best_estimator_.predict(X_test_data)
  auc = roc_auc_score(y_test_data, preds)
  accuracy = accuracy_score(y_test_data, preds)
  precision = precision_score(y_test_data, preds)
  recall = recall_score(y_test_data, preds)
  f1 = f1_score(y_test_data, preds)
  table = pd.DataFrame({'model': [model_name],
                           'precision': [precision],
                           'recall': [recall],
                           'f1': [f1],
                           'accuracy': [accuracy],
                           'AUC': [auc]
                         })
  return table
```

Now use the best performing model to predict on the test set.

```
[57]: # Get predictions on test data
rf1_test_scores = get_scores('random forest1 test', rf1, X_test, y_test)
rf1_test_scores
```

```
[57]: model precision recall f1 accuracy AUC 0 random forest1 test 0.964211 0.919679 0.941418 0.980987 0.956439
```

The test scores are very similar to the validation scores, which is good. This appears to be a strong model. Since this test set was only used for this model, you can be more confident that your model's performance on this data is representative of how it will perform on new, unseeen data.

Feature Engineering You might be skeptical of the high evaluation scores. There is a chance that there is some data leakage occurring. Data leakage is when you use data to train your model that should not be used during training, either because it appears in the test data or because it's not data that you'd expect to have when the model is actually deployed. Training a model with leaked data can give an unrealistic score that is not replicated in production.

In this case, it's likely that the company won't have satisfaction levels reported for all of its employees. It's also possible that the average_monthly_hours column is a source of some data leakage. If employees have already decided upon quitting, or have already been identified by management as people to be fired, they may be working fewer hours.

The first round of decision tree and random forest models included all variables as features. This next round will incorporate feature engineering to build improved models.

You could proceed by dropping satisfaction_level and creating a new feature that roughly

captures whether an employee is overworked. You could call this new feature overworked. It will be a binary variable.

```
[58]: # Drop `satisfaction_level` and save resulting dataframe in new variable
      df2 = df_enc.drop('satisfaction_level', axis=1)
      # Display first few rows of new dataframe
      df2.head()
[58]:
         last_evaluation number_project
                                           average_monthly_hours
                     0.53
                                                                157
                                                                          3
      0
                                         2
                     0.86
                                         5
                                                                262
                                                                          6
      1
      2
                     0.88

[59]: | # Create `overworked` column. For now, it's identical to average monthly hours.
      df2['overworked'] = df2['average_monthly_hours']
      # Inspect max and min average monthly hours values
```

```
print('Max hours:', df2['overworked'].max())
print('Min hours:', df2['overworked'].min())
```

Max hours: 310 Min hours: 96

166.67 is approximately the average number of monthly hours for someone who works 50 weeks per year, 5 days per week, 8 hours per day.

You could define being overworked as working more than 175 hours per month on average.

To make the overworked column binary, you could reassign the column using a boolean mask. - df3['overworked'] > 175 creates a series of booleans, consisting of True for every value > 175 and False for every values 175 - .astype(int) converts all True to 1 and all False to 0

```
[60]: # Define `overworked` as working > 175 hrs/week
df2['overworked'] = (df2['overworked'] > 175).astype(int)

# Display first few rows of new column
df2['overworked'].head()
```

[60]: 0 0 1 1 2 1 3 1 4 0

Name: overworked, dtype: int64

Drop the average_monthly_hours column.

```
[61]: # Drop the `average_monthly_hours` column
df2 = df2.drop('average_monthly_hours', axis=1)

# Display first few rows of resulting dataframe
df2.head()
```

     0 random forest2 cv
                            0.866758   0.878754   0.872407   0.957411   0.96481
     Again, the scores dropped slightly, but the random forest performs better than the decision tree if
     using AUC as the deciding metric.
     Score the champion model on the test set now.
[76]: # Get predictions on test data
      rf2_test_scores = get_scores('random forest2 test', rf2, X_test, y_test)
      rf2_test_scores
[76]:
                       model precision
                                            recall
                                                        f1 accuracy
                                                                            AUC
      0 random forest2 test
                               0.870406 0.903614 0.8867
                                                            0.961641 0.938407
```

This seems to be a stable, well-performing final model.

Plot a confusion matrix to visualize how well it predicts on the test set.

The model predicts more false positives than false negatives, which means that some employees may be identified as at risk of quitting or getting fired, when that's actually not the case. But this is still a strong model.

For exploratory purpose, you might want to inspect the splits of the decision tree model and the most important features in the random forest model.

Decision tree splits

```
[78]: # Plot the tree

plt.figure(figsize=(85,20))

plot_tree(tree2.best_estimator_, max_depth=6, fontsize=14, feature_names=X.

→columns,

class_names={0:'stayed', 1:'left'}, filled=True);
```

Note that you can double-click on the tree image to zoom in on it and inspect the splits.

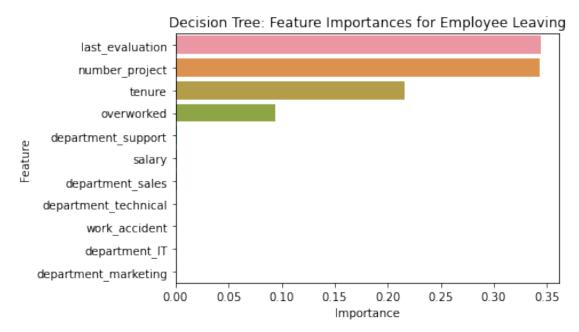

Decision tree feature importance You can also get feature importance from decision trees (see the DecisionTreeClassifier scikit-learn documentation for details).

```
[79]:
                             gini_importance
                                    0.343958
      last_evaluation
      number_project
                                    0.343385
      tenure
                                    0.215681
      overworked
                                    0.093498
      department_support
                                    0.001142
                                    0.000910
      salary
      department_sales
                                    0.000607
      department_technical
                                    0.000418
      work_accident
                                    0.000183
      department_IT
                                    0.000139
      department_marketing
                                    0.000078
```

You can then create a barplot to visualize the decision tree feature importances.

```
[80]: sns.barplot(data=tree2_importances, x="gini_importance", y=tree2_importances.

→index, orient='h')
```

The barplot above shows that in this decision tree model, last_evaluation, number_project, tenure, and overworked have the highest importance, in that order. These variables are most helpful in predicting the outcome variable, left.

Random forest feature importance Now, plot the feature importances for the random forest model.

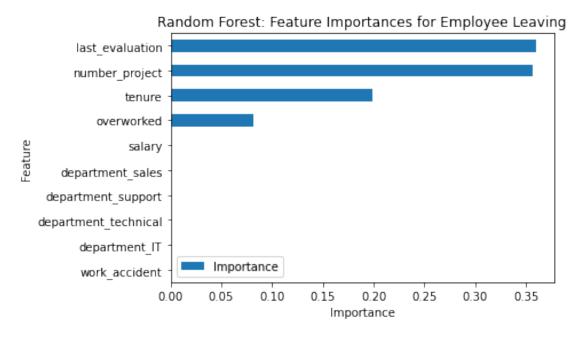

```
[81]: # Get feature importances
    feat_impt = rf2.best_estimator_.feature_importances_

# Get indices of top 10 features
    ind = np.argpartition(rf2.best_estimator_.feature_importances_, -10)[-10:]

# Get column labels of top 10 features
    feat = X.columns[ind]

# Filter `feat_impt` to consist of top 10 feature importances
    feat_impt = feat_impt[ind]

y df = pd.DataFrame({"Feature":feat,"Importance":feat_impt})
```

The plot above shows that in this random forest model, last_evaluation, number_project, tenure, and overworked have the highest importance, in that order. These variables are most helpful in predicting the outcome variable, left, and they are the same as the ones used by the decision tree model.

3 pacE: Execute Stage

- Interpret model performance and results
- Share actionable steps with stakeholders

Recall evaluation metrics

• AUC is the area under the ROC curve; it's also considered the probability that the model ranks a random positive example more highly than a random negative example.

- **Precision** measures the proportion of data points predicted as True that are actually True, in other words, the proportion of positive predictions that are true positives.
- Recall measures the proportion of data points that are predicted as True, out of all the data points that are actually True. In other words, it measures the proportion of positives that are correctly classified.
- Accuracy measures the proportion of data points that are correctly classified.
- **F1-score** is an aggregation of precision and recall.

Reflect on these questions as you complete the executing stage.

- What key insights emerged from your model(s)?
- What business recommendations do you propose based on the models built?
- What potential recommendations would you make to your manager/company?
- Do you think your model could be improved? Why or why not? How?
- Given what you know about the data and the models you were using, what other questions could you address for the team?
- What resources do you find yourself using as you complete this stage? (Make sure to include the links.)
- Do you have any ethical considerations in this stage?

3.1 Step 4. Results and Evaluation

- Interpret model
- Evaluate model performance using metrics
- Prepare results, visualizations, and actionable steps to share with stakeholders

3.1.1 Summary of model results

Logistic Regression

The logistic regression model achieved precision of 80%, recall of 83%, f1-score of 80% (all weighted averages), and accuracy of 83%, on the test set.

Tree-based Machine Learning

After conducting feature engineering, the decision tree model achieved AUC of 93.8%, precision of 87.0%, recall of 90.4%, f1-score of 88.7%, and accuracy of 96.2%, on the test set. The random forest modestly outperformed the decision tree model.

3.1.2 Conclusion, Recommendations, Next Steps

The models and the feature importances extracted from the models confirm that employees at the company are overworked.

To retain employees, the following recommendations could be presented to the stakeholders:

- Cap the number of projects that employees can work on.
- Consider promoting employees who have been with the company for atleast four years, or conduct further investigation about why four-year tenured employees are so dissatisfied.
- Either reward employees for working longer hours, or don't require them to do so.
- If employees aren't familiar with the company's overtime pay policies, inform them about this. If the expectations around workload and time off aren't explicit, make them clear.

- Hold company-wide and within-team discussions to understand and address the company work culture, across the board and in specific contexts.
- High evaluation scores should not be reserved for employees who work 200+ hours per month. Consider a proportionate scale for rewarding employees who contribute more/put in more effort.
